COEFFICIENTS IN POLYNOMIAL IDENTITY FOR ODD POWERS

PETRO KOLOSOV

ABSTRACT. https://mathoverflow.net/q/485764/113033

1. Introduction

It is widely known fact that finite difference of cubes can be expressed in terms of triangular numbers

$$\Delta n^3 = (n+1)^3 - n^3 = 1 + 6 \binom{n+1}{2}$$

where $\binom{n+1}{2}$ are triangular numbers. Apart that, triangular numbers themselves are equivalent to the sum of first n non-negative integers

$$\binom{n+1}{2} = \sum_{k=0}^{n} k$$

Which leads to identity in terms of finite differences of cubes

$$\Delta n^3 = (n+1)^3 - n^3 = 1 + 6\sum_{k=0}^{n} k$$

It is obvious that n^3 evaluates to the sum of its n-1 finite differences, so that

$$\Delta n^3 = \sum_{k=0}^{n-1} \Delta k^3 = \sum_{k=0}^{n-1} \left(1 + 6 \sum_{t=0}^k t \right)$$
 (1)

In its explicit form

$$n^{3} = [1 + 6 \cdot 0] + [1 + 6 \cdot 0 + 6 \cdot 1] + [1 + 6 \cdot 0 + 6 \cdot 1 + 6 \cdot 2]$$

$$+ \dots + [1 + 6 \cdot 0 + 6 \cdot 1 + 6 \cdot 2 + \dots + 6 \cdot (n-1)]$$
(2)

We could use Faulhaber's formula on $\sum_{t=0}^{k} t$ in (1), which leads to well known and expected identity in cubes $n^3 = \sum_{k=0}^{n-1} \sum_{t=0}^{2} {3 \choose t} k^t$.

Instead, let's rearrange the terms in (2) to get

$$n^{3} = n + [(n-0) \cdot 6 \cdot 0] + [(n-1) \cdot 6 \cdot 1] + [(n-2) \cdot 6 \cdot 2]$$
$$+ \dots + [(n-k) \cdot 6 \cdot k] + \dots + [1 \cdot 6 \cdot (n-1)]$$

By applying compact sigma sum notation yields an identity for cubes n^3

$$n^{3} = n + \sum_{k=0}^{n-1} 6k(n-k)$$

The term n in the sum above can be moved under sigma notation, because there is exactly n iterations, therefore

$$n^{3} = \sum_{k=0}^{n-1} 6k(n-k) + 1$$
 (3)

By inspecting the expression 6k(n-k)+1 we iterate under summation, we can notice that it is symmetric over k, let be T(n,k)=6k(n-k)+1, then

$$T(n,k) = T(n,n-k)$$

This symmetry allows us to alter summation bounds again, so that

$$n^{3} = \sum_{k=1}^{n} 6k(n-k) + 1 \qquad (4)$$

Assume that polynomial identities $n^3 = \sum_{k=0}^{n-1} 6k(n-k) + 1$ and $n^3 = \sum_{k=1}^{n} 6k(n-k) + 1$ have explicit form as follows

$$n^{3} = \sum_{k} A_{1,1}k^{1}(n-k)^{1} + A_{1,0}k^{0}(n-k)^{0}$$

where $A_{1,1} = 6$ and $A_{1,0} = 1$, respectively.

It could be generalized even further, for every odd power 2m + 1, giving a set of real coefficients $A_{m,0}, A_{m,1}, A_{m,2}, A_{m,3}, \ldots, A_{m,m}$ such that

$$n^{2m+1} = \sum_{k=1}^{n} A_{m,0} k^{0} (n-k)^{0} + A_{m,1} k^{1} (n-k)^{1} + \dots + A_{m,m} k^{m} (n-k)^{m}$$
 (5)

Leading to numerous polynomial identities, including its compact form

$$n^{2m+1} = \sum_{r=0}^{m} \sum_{k=1}^{n} A_{m,r} k^r (n-k)^r; \quad n^{2m+1} = \sum_{r=0}^{m} \sum_{k=0}^{n-1} A_{m,r} k^r (n-k)^r$$

For example,

$$n^{3} = \sum_{k=1}^{n} 6k(n-k) + 1$$

$$n^{5} = \sum_{k=1}^{n} 30k^{2}(n-k)^{2} + 1$$

$$n^{7} = \sum_{k=1}^{n} 140k^{3}(n-k)^{3} - 14k(n-k) + 1$$

$$n^{9} = \sum_{k=1}^{n} 630k^{4}(n-k)^{4} - 120k(n-k) + 1$$

$$n^{11} = \sum_{k=1}^{n} 2772k^{5}(n-k)^{5} + 660k^{2}(n-k)^{2} - 1386k(n-k) + 1$$

These coefficients $A_{m,r}$ are registered in OEIS: https://oeis.org/A302971, https://oeis.org/A304042.

Recurrence relation for $A_{m,r}$ is given by: https://mathoverflow.net/q/297900/113033

Question 1: The algorithm we used to obtain identities for cubes (3), (4) is quite simple, if not naive. I believe it should be discussed in mathematical literature, as well as identity that gives a set of real coefficients $A_{m,r}$ such that

$$n^{2m+1} = \sum_{k=1}^{n} A_{m,0} k^{0} (n-k)^{0} + A_{m,1} (n-k)^{1} + \dots + A_{m,m} k^{m} (n-k)^{m}$$

However, I was not able to find any references that in particular mention coefficients $A_{m,r}$, which is one of open questions.

Question 2: Can we consider the process of obtaining the identities (3), (4) as an interpolation technique?

Question 3: If the question 2 is true, can we consider equation (5) as an interpolation technique too?
